**Insulin Injection Sites**

**NOTE:** It is really important to change (rotate) where you give yourself insulin to prevent fatty lumps from forming since these can affect how your body absorbs insulin. For example, you can move from one side of your abdomen to the other side, and you can also move your injection site to a different location within each side of your abdomen.

Avoid a 2-inch area around the belly button as well as scar tissue.

---

**Insulin Pens:**

Your pen comes with an instruction book. Please review it to understand how your pen works, how to load the cartridge, and how to prepare your pen for an insulin injection. There are different sizes and lengths of needle tips available. Most often the shortest needle is recommended. Talk with your health care professional about which needle tip would be best for you.

**Mixing Insulin:**

Insulin that is cloudy (NPH, premixed) needs to be mixed before using. The pen should be rolled ten times, tipped ten times, and checked for a milky-white consistency.

**Check Insulin Flow (Prime):**

Attach pen needle. Dial up 2 or 3 units (whichever the manufacturers recommends) and, with pen tip facing upwards, push the dosing button. If no stream of insulin appears, repeat this step again.

**Giving Your Injection:**

After you have checked the insulin flow, dial up the dose of insulin to be taken. Insert pen tip into skin at a 90º angle. Push the dosing button until you see ‘0’. Count 10 seconds before removing the needle from your skin to ensure you receive the full dose. With longer needles (≥ 8mm), you may need to gently lift the skin before injection or inject on an angle.

### Site | Things to think about
--- | ---
**Abdomen (tummy)**
Stay 2 inches (5 cm) away from your belly button | Easy to reach. Insulin absorbs fast and consistently.

**Buttock and thigh** | Slower absorption rate than from abdomen and arm sites.

**Outer arm** | After abdomen, arm provides the next fastest absorption rate. This area is hard to reach when injecting yourself, so it is often not recommended.

# Insulin Care and Storage:

Unopened insulin should be stored in the fridge between 2°C and 8°C. The insulin you are using can be stored at room temperature for up to 1 month. Both Levemir and Toujeo are the exception; they are safe at room temperature for 42 days. Discard insulin that has been frozen or exposed to temperatures greater than 30°C. Do not use insulin after its expiry date.

# Diabetes Identification:

You should always wear identification, such as a bracelet or necklace, to identify that you have diabetes. Identification bracelets, such as MedicAlert®, can be purchased at pharmacies and jewellery stores. Always carry identification in your wallet or purse that provides information about your diabetes.
Low Blood Sugars (Hypoglycemia):

**Treatment of Low Blood Glucose (Hypoglycemia)**

**What is low blood glucose?**
When the amount of blood glucose (sugar in your blood) has dropped below your target range (i.e. is generally less than 4.0 mmol/L), a condition called low blood glucose or hypoglycemia occurs.

**When this happens, you may feel:**
- Shaky, light-headed, nauseated
- Nervous, irritable, anxious
- Confused, unable to concentrate
- Hungry
- A faster heart rate
- Sweaty, headachy
- Weak, drowsy
- A numbness or tingling in your tongue or lips

**How do I treat low blood glucose?**
If you are experiencing the signs of a low blood glucose level, check your blood glucose immediately. If you do not have your meter with you, treat the symptoms anyway. It is better to be safe.

Eat or drink a fast-acting carbohydrate source (containing 15 grams). For example:
- 15 g of glucose in the form of glucose tablets (preferred choice)
- 15 mL (1 tablespoon) or 3 packets of table sugar dissolved in water
- 175 mL (¾ cup) of juice or regular soft drink
- 6 LifeSavers® (1 = 2.5 g of carbohydrate)
- 15 mL (1 tablespoon) of honey (do not use for children less than 1 year)

Low blood glucose can happen quickly, so it is important to treat it right away. If your blood glucose drops very low, you may need help from another person.

**Causes of hypoglycemia:**
- More physical activity than usual
- Taking too much medication
- Not eating on time
- Drinking alcohol
- Eating less than usual

Insulin

SMBG pattern*

* SMBG = self-monitoring of blood glucose

For more information about checking your blood glucose, visit the Self-monitoring of Blood Glucose tool on guidelines.diabetes.ca, under Patient Resources.
Proper Use of Pen Tips (needles):

Use pen tips only once; they are thin and can become bent or broken if re-used. Reusing pen tips can make the injection more painful. Leaving pen tips on the cartridge may cause leaking or allow air into the cartridge which may affect the concentration of the insulin.

Safe Sharps Disposal:

Pen tips and lancets should be disposed of in a sharps container. Check with your local pharmacy. Many pharmacies supply safe, puncture-proof containers. When the container is full, it is returned to the pharmacy in exchange for a new container. Sharps otherwise should be disposed of in accordance with local regulations.

Diabetes Driving Guidelines

Prevention of hypoglycemia for all insulin-treated drivers

• Measure your blood glucose level immediately before and at least every 4 hours during long drives.
• Always carry blood glucose monitoring equipment and treatment for hypoglycemia (e.g. source of fast-acting carbohydrate) within easy reach (e.g. attached to the visor).
• You should not drive when your blood glucose level is less than 4.0 mmol/L. If your blood glucose level is less than 4.0 mmol/L, you should have some carbohydrate-containing food and not begin to drive until your blood glucose level is at least 5.0 mmol/L.
• Stop and treat yourself as soon as hypoglycemia and/or impaired driving is suspected. You should not drive for at least 45 minutes after effective treatment of mild to moderate hypoglycemia (i.e. blood glucose level 2.5 – 4.0 mmol/L).

Professional Drivers

• You should follow the above recommendations as well as perform any diabetes self care as required by your licensing province.

Each province has its own rules regarding glucose control and being able to drive.

I want to apply for a commercial licence.

Can I drive in Canada? In the United States?

Canadians with diabetes who are using insulin can apply for a commercial licence. Motor vehicle licensing authorities require a greater level of medical fitness for drivers operating passenger vehicles (buses/commercial vans), trucks, and emergency vehicles. Commercial drivers spend more time driving and are often under more adverse conditions than private drivers.

Canadians with diabetes who are using insulin can be licensed to drive a commercial vehicle in Canada. The Canada/US Medical Reciprocity Agreement (effective March 1999) recognizes the similarity between Canadian and American medical standards and provides for reciprocal arrangements on medical fitness requirements for Canadian and American drivers of commercial vehicles.

However, Canadian commercial drivers who have diabetes requiring insulin, are not permitted to drive in the United States.

What is Diabetes Canada’s position on diabetes and driving and licensing?

Diabetes Canada believes people with diabetes should be assessed for a driver’s licence on an individual basis.
